Strongly Connected Components  
BFS  
Shortest paths

Directed paths

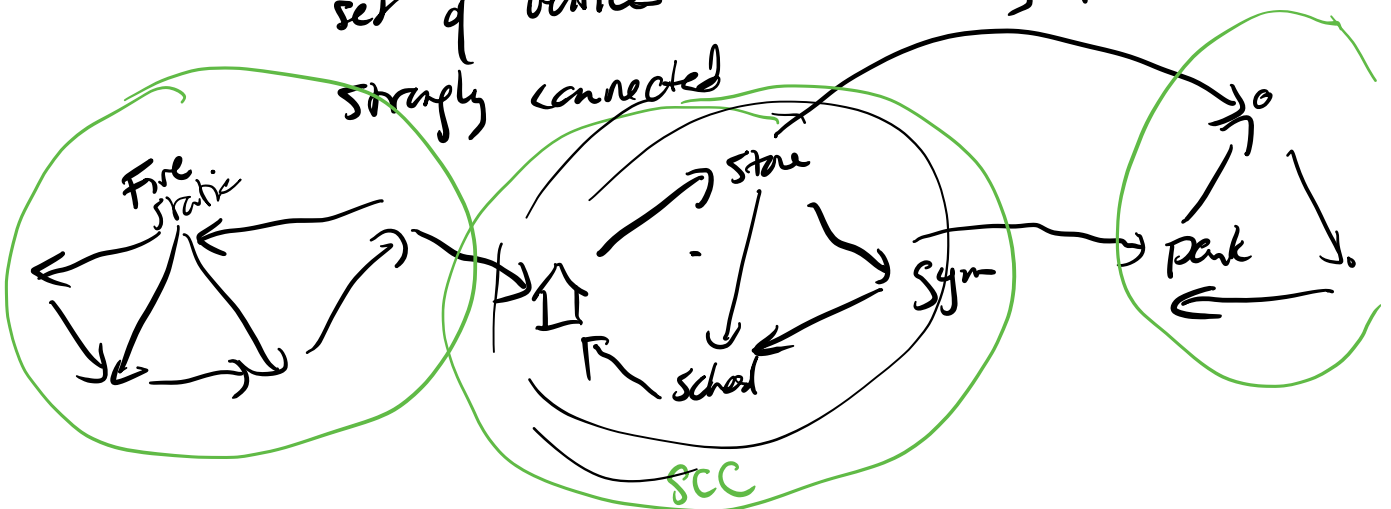

Start at  $v$  + do DFS

What is discovered from explore depends  
on where you start

Def: Vertices  $u$  +  $v$  are strongly connected  
if  $\exists$  a path from  $u$  to  $v$  + from  $v$  to  $u$ .

Def: A strongly connected component is the  
set of vertices so that every pair is  
strongly connected

→ strongly connected components

In general, any directed graph is a  
DAG (Directed acyclic graph) of SCC.

We can get this structure from DFS!

DFS: Start anywhere.

Property 1: Explore from  $u$  stops when all vertices from  $u$  are reached

Property 2: The vertex with highest post # is in a source SCC

(Recall every DAG has  $\geq$  source  $\rightarrow$  sink)

PF  
Case 1: We visit  $u$  before  $v$  in DFS  
If I see  $u$ , I will see  $v$  during same explore subroutine, regardless of where I started.

Then we finish exploring  $v$ 's SCC before we postvisit  $u$ .

(alt:  $u$  is on the stack + all of  $v$ 's SCC is popped off stack before  $u$  is popped off)

Case 2: We visit  $v$  before  $u$

If we visit  $v$ , we visit  $v$ 's SCC

all SCCs reachable from  $v$ .

But this cannot include  $u$ 's SCC  
or we have a cycle (in metagraph  
of SCCs)

Finish explore  
before exploring + reaching  $u$

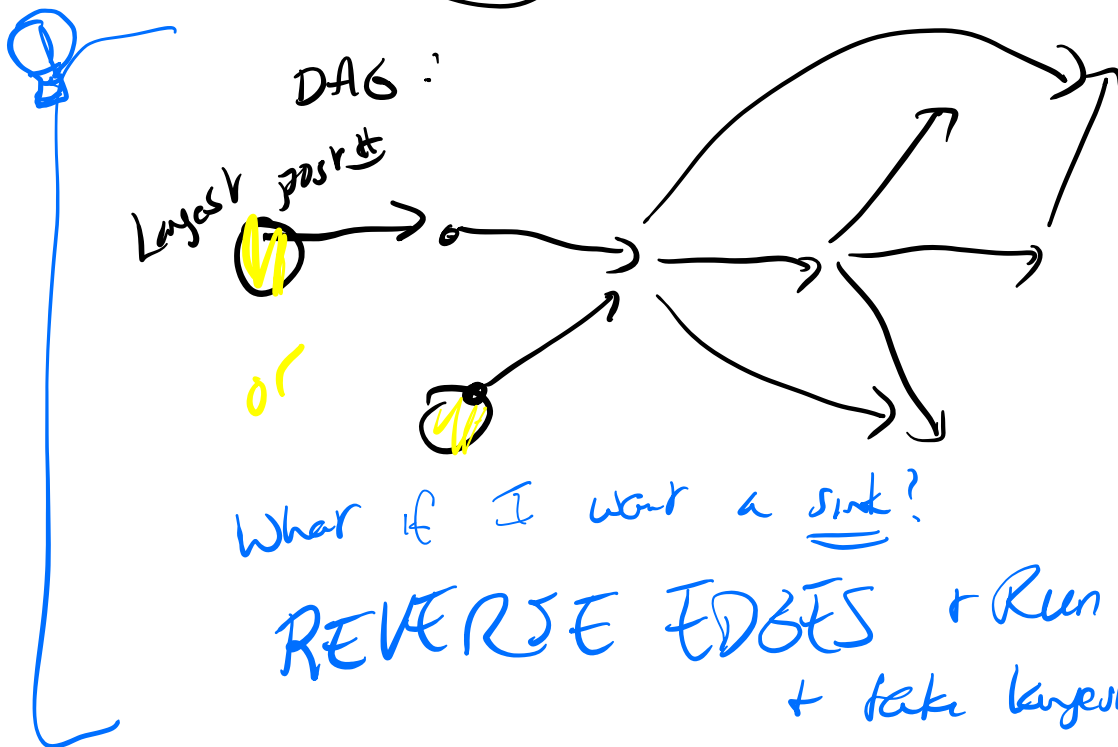

So  $v$  gets a post# before  $u$   
gets a previsit# + therefore  
 $post(u) > post(v)$

Obs.

1. So, to find DAG of SCCs, we want  
to start in a sink SCC  
because we find that SCC + nothing  
else + we can remove it + repeat

2. We know the vertex with highest post#  
is in a source SCC.

??

1. Reverse edges to get  $G^R$
2. Run DFS on  $G^R$
3. Vertex with largest post# is in a source SCC of  $G^R$   
+ this is a sink SCC of  $G$ .

Alg:  
 • Run DFS on  $G^R$  ← Just to get post#  
 • Explain from vertex  $n$  is largest post#  
 That is a Sink SCC.  
 Remove it.  
 Repeat.

↑  
 vertex with largest post#  
 in remaining vertices (from  
 original DFS of  $G^R$ )

is now in a Sink SCC  
 of what's remaining!

Total running time?

DFS on  $G^R$

$O(n+m)$

DFS on G

Very fast!

$O(n+m)$

$O(n+m)$

BFS

Explore from 1. (root)  
Then explore from everything reachable from 1

We use a queue Q

Queue  
entries

1

procedure bfs ( $G, s$ )

Input is  $G=(V, E)$  (directed or undirected)

Vertex  $s \in V$

Output all vertices  $u$  reachable from  $s$ ,

$\text{dist}(u)$  is a set of distances

for all  $u \in V$ ,  $\text{dist}(u) = \infty$  initialize

$\text{dist}(s) = 0$

$Q = \{s\}$

while  $Q$  is not empty:

$u = \text{eject}(Q)$

for all edges  $(u, v) \in E$

if  $\text{dist}(v) = \infty$

inject( $Q, v$ )

$\text{dist}(v) = \text{dist}(u) + 1$

BFS gives shortest distances  
from  $s$ . Fewest hops

if  $\text{dist}(u) = 4 \Rightarrow$

there is a path with 4 hops

& there is not a shorter one.

Weighted graphs.

What is the best way to get  
from  $x$  to  $y$ ?

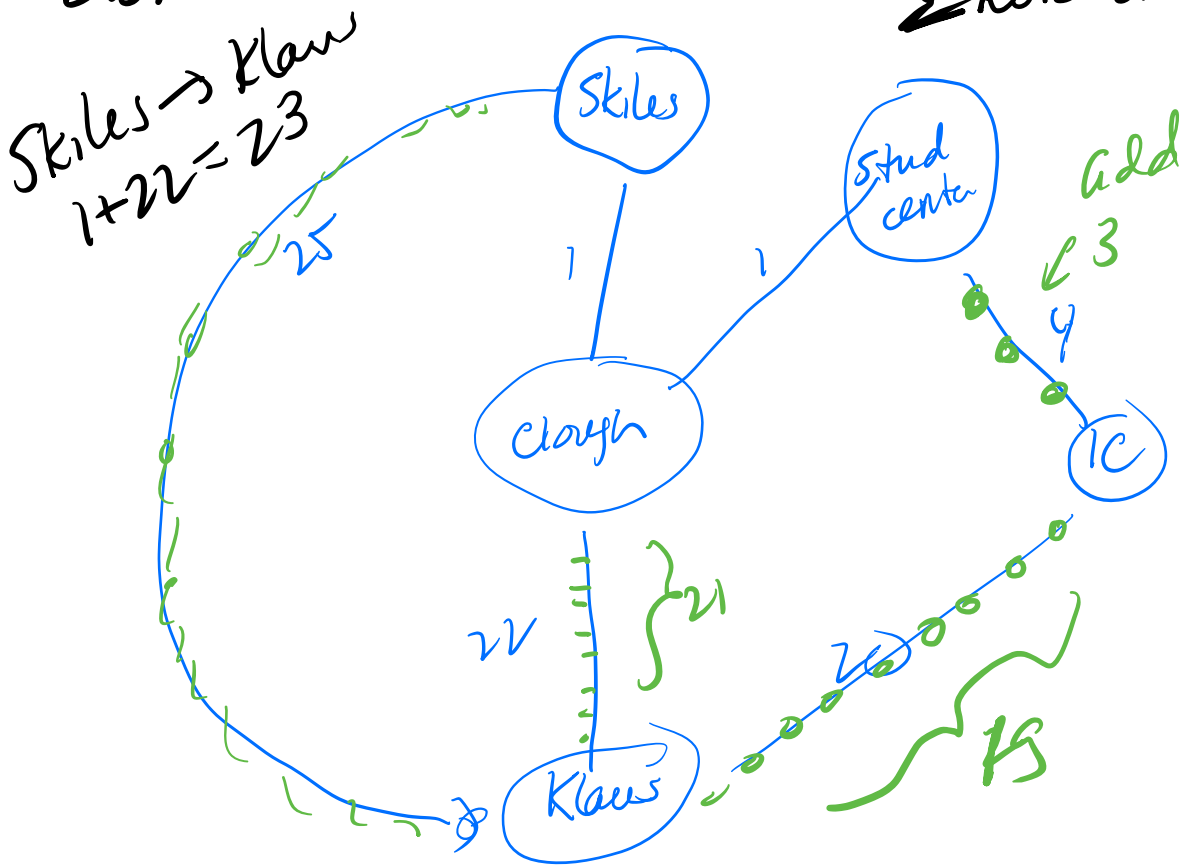

$w(u,v)$  is the weight of edge

between  $u$  +  $v$

Assume  $w(u,v) \geq 0, \forall u,v$

(nonnegative weights)

Dist between  $u$  &  $v$  is min cost path  
 $\sum \text{weights on edges}$

Can I use BFS to find shortest distance (from Skiles) ?  
In all else

Add dummy vertex!

BFS on this new graph gives  
shortest distances!

Instead: Find next interesting  
event (not dummy vtes)
